We consider abstract parabolic problems in ordered Banach spaces and give conditions under which they possess global attractors. Our approach goes via comparison of solutions. Within this approach abstract comparison principles are obtained and bounds on the attractors are given by order intervals in Banach spaces. These results are applied to ordinary differential equations and to parabolic equations for which the main part is given by a sum of fractional powers of sectorial operators having increasing resolvent and integral operators having positive kernels.

1. INTRODUCTION

Let \( X \) be a Banach space and \( A : D(A) \subset X \to X \) be a \textit{sectorial operator}. Choose \( \lambda_0 \in \mathbb{R} \) such that \( \text{Re}(\sigma(A)) > \lambda_0 \); that is, \( \text{Re}(\lambda) > \lambda_0 \) for all \( \lambda \in \sigma(A) \) (\( \sigma(A) \) is the spectrum of \( A \)). As usual \( X^\alpha \) ([13, p. 29]) denote the \textit{fractional power spaces} associated to \( A \). Assume that \( f : X^\alpha \to X \) is Lipschitz continuous in bounded subsets of \( X^\alpha \) and consider the following abstract parabolic initial value problem

\[
\begin{align*}
\dot{u} + Au &= f(u), \\
u(0) &= u_0 \in X^\alpha.
\end{align*}
\]

(1)

Under these assumptions the problem (1) is locally well posed in \( X^\alpha \) (see [13], Theorem 3.3.4), the solution \( u(t, u_0) \) of (1) is defined in a maximal interval of existence \([0, \tau_{u_0})\) and either \( \tau_{u_0} = +\infty \) or \( \limsup_{t \to \tau_{u_0}^-} \|u(t, u_0)\|_{X^\alpha} < \infty \). When \( X \) is a Hilbert space, to

† Partially supported by grant KNB # 2 P03A 035 18, Poland.
ensure that the problem (1) is globally well posed, the usual approach is to obtain some energy estimates for the solutions. We are interested in the case when $X$ is not a Hilbert space and in that case different tools to obtain bounds on the solutions are needed. The tools that we will use to replace energy estimates are abstract comparison results. For that we need some additional structure to the abstract problem. We start with the following definitions.

**Definition 1.1.** An ordered Banach space is a pair $(X, \leq)$, where $X$ is a Banach space and $\leq$ is an ordering relation in $X$ satisfying

1. $x \leq y$ implies $x + z \leq y + z$, $x, y, z \in X$,
2. $x \leq y$ implies $\lambda x \leq \lambda y$, $x, y \in X$, and $0 \leq \lambda \in \mathbb{R}$.
3. the positive cone $C = \{x \in X : x \geq 0\}$ is closed in $X$ (where $x \geq y$ means $y \leq x$).

**Definition 1.2.** Let $(X, \leq_X)$ and $(Y, \leq_Y)$ be ordered Banach spaces. A function $T : X \to Y$ is increasing iff $x_1 \leq_X x_2$ implies $T(x_1) \leq_Y T(x_2)$ and it is positive iff $x \geq_X 0$ implies $T(x) \geq_Y 0$.

Note that the notions in Definition 1.2 coincide when the map $T$ is linear.

**Definition 1.3.** Let $X$ be an ordered Banach space. A vector $\xi \in X$ is said to be an upper bound for $B \subset X$ if $b \leq \xi$ for any $b \in B$. In an ordered Banach space, if $a \leq b$, the set $[a, b] = \{x \in X : a \leq x \leq b\}$ is called an order interval.

For the rest of this section we assume that $X$ is an ordered Banach space. Assume that $(\lambda + A)^{-1}$ is increasing for all $\mathbb{R} \ni \lambda > \lambda_0$. Assume also that there are numbers $c_1^+, c_1^- \in \mathbb{R}$ and vectors $X \ni c_2^+, c_2^- \geq 0$, such that the map $f$ satisfies

\begin{align*}
  f(u) &\leq c_1^+ u + c_2^+, \quad u \geq 0, \\
  f(u) &\geq c_1^- u + c_2^-, \quad u \leq 0. \\
\end{align*}

Under these assumptions and some regularity we prove that the solutions of the problem (1) are globally defined. If in addition to the above hypothesis we assume that the Re$\sigma(A - c_1^+ I) > 0$, then the problem (1) has a global attractor.

This paper is organized as follows. In Section 2 we give introductory results concerning positivity and comparison, which will be of help when proving the desired result on the asymptotics of (1). In Section 3 we prove existence of global attractors. In Section 4 we give several examples of equations for which the abstract results developed in Section 3 apply, among them we include results on ordinary differential equations, parabolic equations with pseudo-differential operators and integral-pseudodifferential equations. Finally, in the Appendix we state several results which enable us to say that a given operator has increasing resolvent as well as to produce new operators with increasing resolvent starting from operators for which this property is known.

2. ABSTRACT MONOTONICITY AND COMPARISON

In this section we follow [6] to establish abstract comparison results for parabolic problems of the form (1), assuming that the base space $X$ is an ordered Banach space and that the resolvent of $A$ is increasing, i.e. $(\lambda + A)^{-1}$ is increasing for all $\lambda > \lambda_0$.

2.1. Nonlinear Perturbations of Increasing Resolvent Operators

We start from positivity and comparison results for nonlinear equations

\[ \dot{u} + Au = f(t, u), \quad u(t_0) = u_0 \in X^\alpha, \]

where $f : [t_0, t_1] \times X^\alpha \to X$ is locally Hölder in $t$, locally Lipschitz in $u$ and $0 \leq \alpha < 1$. The unique solution of (3) (see [13], [18]) is denoted by $u_f(t, u_0)$. All the initial value problems studied below will be such that the nonlinearity satisfies the above condition.

Concerning positivity, we have

**Theorem 2.1.** Let $(X, \leq)$ be an ordered Banach space and $A$ a sectorial operator in $X$ with increasing resolvent. Assume that for every $r > 0$ there exists a constant $\beta = \beta(r) > 0$ such that $f(t, \cdot) + \beta I$ is positive, for each $t \in [t_0, t_1)$, in the ball of radius $r$ in $X^\alpha$. If $u_0 \geq 0$, then $u_f(t, u_0)$ is positive while it exists.

Concerning comparison, we have

**Theorem 2.2.** Let $(X, \leq)$ be an ordered Banach space, and $A$ be a sectorial operator with increasing resolvent.

i) If for every $r > 0$ there exits $\beta = \beta(r) > 0$ such that for $t \in [t_0, t_1]$, $f(t, \cdot) + \beta I$ is increasing in a ball of radius $r$ in $X^\alpha$, then $u_0 \geq u_1$ implies $u_f(t, u_0) \geq u_f(t, u_1)$ as long as both solutions exist.

ii) If $f(t, \cdot) \geq g(t, \cdot)$ for every $t$, then $u_f(t, u_0) \geq u_g(t, u_0)$ as long as both solutions exist.

iii) If for every $r > 0$ there exists $\beta(r) > 0$ and an increasing function $h(t, \cdot)$ such that $f(t, \cdot) + \beta I \geq h(t, \cdot) \geq g(t, \cdot) + \beta I$ in a ball of radius $r$, then $u_0 \geq u_1$ implies $u_f(t, u_0) \geq u_g(t, u_1)$ as long as both solutions exist.

The proof of the above results are based on the studies of successive approximations.

2.2. Quasi-monotone Maps and Increasing Resolvent Matrices
In what follows we mention how Theorem 2.2 relates to the classical results concerning ordinary differential equation in $R^n$ having the form

$$\frac{d}{dt} \vec{z} = F(\vec{z}),$$

$$\vec{z}(0) = \vec{z}_0.$$  \hspace{1cm} (4)

We aim to give conditions on the vector field $F$ implying that the solution operator for (4) is increasing with respect to initial conditions. The approach is the one used by J. Szarski in [19] (see also [17, 22]).

Let $\vec{x} = (x_1, \cdots, x_n)$ and $\vec{y} = (y_1, \cdots, y_n)$ be vectors in $\mathbb{R}^n$. We write

$$\vec{x} \leq \vec{y}, \quad \text{if} \quad x_j \leq y_j, \quad j = 1, \cdots, n$$

and

$$\vec{x}^i \leq \vec{y}, \quad \text{if} \quad x_j \leq y_j, \quad j = 1, \cdots, n \quad \text{and} \quad x_i = y_i.$$

We say that $F: \mathbb{R}^n \to \mathbb{R}^n$ is quasi-monotone increasing if

$$\vec{x} \leq \vec{y} \Rightarrow F_i(\vec{x}) \leq F_i(\vec{y}), \quad i = 1, \ldots, n.$$  \hspace{1cm} \text{Theorem 2.3.}

If $F$ is a locally Lipschitz function which is quasi-monotone increasing, $\vec{x}_0 \leq \vec{y}_0 \in \mathbb{R}^n$, $\vec{x}(t, \vec{x}_0)$ and $\vec{y}(t, \vec{y}_0)$ are the solutions of (4) starting at $\vec{x}_0$ and $\vec{y}_0$ respectively, then

$$\vec{x}(t, \vec{x}_0) \leq \vec{y}(t, \vec{y}_0)$$

for as long as both solutions exist.

\textbf{Proof}: Since for any bounded set $B$ there is a constant $L_B > 0$ such that $F + L_B I$ is increasing in $B$, the result follows from Theorem 2.2. \hfill \Box

If $F(\vec{x}) = A\vec{x}$ with $A$ being an $n \times n$ matrix, then requiring that $F$ is quasi-monotone increasing is equivalent to the requiring that all off-diagonal terms of $A$ are nonnegative. Hence we have the following corollary

\textbf{Corollary 2.1.} Let $A$ be an $n \times n$ matrix with non-negative off-diagonal entries. Then $e^{At} \geq 0$, $t \geq 0$.

This enables us to construct many examples of finite dimensional operators with increasing resolvent.

\textbf{3. ORDER AND ATTRACTORS}

With the aid of considerations of Section 2 we prove in this section the results stated in the introduction.
3.1. Basic Estimates

We start with simple lemmas from the theory of semigroups.

**Lemma 3.1.** Let $A$ be a sectorial operator in a Banach space $X$ and, for $c_1 \in \mathbb{R}$, consider the linear problem

$$
\dot{u} + Au - c_1 u = 0, \\
u(0) = u_0.
$$

For every $T > 0$ there exists $M = M(T, c_1)$ such that if $u_0 \in X^\beta$ and $\alpha \geq \beta$ then

$$
\|u(t)\|_{X^\alpha} \leq Mt^{-(\alpha - \beta)}\|u_0\|_{X^\beta}
$$

for every $t \in (0, T]$. Moreover, if $\text{Re}\sigma(A - c_1 I) > \mu_1 > 0$, then we can take $T = \infty$ and replace $M$ by $M_0 e^{-\mu_1 t}$.

**Lemma 3.2.** Suppose that $A$ and $X$ are as in Lemma 3.1, $\text{Re}\sigma(A - c_1 I) > \mu_1 > 0$ and consider the equation

$$
\dot{w} + Aw = c_1 w + c_2, \\
w(0) = w_0.
$$

Let $\phi = (A - c_1)^{-1}c_2$ and assume that

- $\phi \in Y$,
- there is $\alpha_0 > 0$ (which may be greater then $1$) such that $\|x\|_Y \leq c_Y \|x\|_{X^{\alpha_0}}, \ x \in X^{\alpha_0}$.

If $w(t, w_0)$ denotes the solution of (5), then there are positive constants $M$ and $K$ such that,

$$
\|w(t, w_0)\|_Y \leq Mt^{-\alpha_0}\|w_0 - \phi\|_X + K, \ t > 0.
$$

**Proof:** Consider the following change of variables: $w = v + \phi$ where $\phi$ is the solution of

$$
A\phi - c_1 \phi - c_2 = 0.
$$

Then, $v$ satisfies

$$
\dot{v} + Av = c_1 v, \\
v(0) = w_0 - \phi.
$$

From Lemma 3.1 and the embedding of $X^{\alpha_0}$ into $Y$ we have

$$
\|w(t, w_0)\|_Y \leq c_Y M_0 t^{-\alpha_0}\|w_0 - \phi\|_X + \|\phi\|_Y, \ t > 0
$$

3.2. B-monotone Maps

In Subsection 2.1 we mentioned the maps \( f \) with the property that given a bounded set \( B \) in the domain of \( f \), there is a constant \( \beta_B > 0 \) such that \( f + \beta_B I \) is increasing in \( B \). These maps will be called \( B \)-monotone maps.

We start studying the behavior of solutions of parabolic problems of the form

\[
\begin{align*}
\dot{u} + Au &= f(u), \\
u(0) &= u_0,
\end{align*}
\]

where \((X, \geq)\) is an ordered Banach space, \( A \) is a sectorial operator with increasing resolvent and \( f : X^\alpha \to X \) is Lipschitz continuous on bounded sets for some \( \alpha \in [0,1) \).

Consider the following auxiliary problem

\[
\begin{align*}
\dot{u} + Au &= f^+(u),
\end{align*}
\]

where \( f^+ \) is Lipschitz continuous in bounded subsets of \( X^\alpha \) satisfying

\[
f(u) \leq f^+(u), \quad u \in X^\alpha.
\]

Under these assumptions it follows immediately from Theorem 2.2 that

**Lemma 3.3.** If either \( f \) or \( f^+ \) be \( B \)-monotone and \( u_0 \leq u_1 \), then

\[
uf(t, u_0) \leq uf^+(t, u_1)
\]

for as long as \( uf(t, u_0) \) and \( uf^+(t, u_1) \) exist.

3.3. Attractors and Bounds

We are now prepared to prove existence of attractors for (1) and obtain bounds for them.

Assume that \( A \) is a sectorial operator in an ordered Banach space \( X \) and, for some \( \alpha \in [0,1) \), \( f : X^\alpha \to X \) is Lipschitz continuous in bounded sets \( B \)-monotone function. Assume also that (2) holds and for any \( u_0 \in X^\alpha \) there are \( u_0^+, u_0^- \in X^\alpha \) satisfying \( u_0^- \leq u_0 \leq u_0^+ \) and \( u_0^+ \geq 0, -u_0^- \geq 0 \).

Consider the problem (8) and a pair of auxiliary problems

\[
\begin{align*}
\dot{u}^+ + Au^+ &= c_1^+ u^+ + c_2^+, \\
u^+(0) &= u_0^+,
\end{align*}
\]

\[
\begin{align*}
\dot{u}^- + Au^- &= c_1^- u^- + c_2^-, \\
u^-(0) &= u_0^-.
\end{align*}
\]

Let \( u(t, u_0), u^+(t, u_0^+) \) and \( u^-(t, u_0^-) \) denote the solutions of (8), (12) and (13) respectively. Since from Lemma 3.3 \( u^+(t, u_0^+) \geq 0 \), we have that

\[
u(t, u_0) \leq u^+(t, u_0^+),\]
for as long as \(u(t, u_0)\) exists. Proceeding similarly in the case of \(u^-\), we get

\[
- (t, u^-_0) \leq u(t, u_0) \leq + (t, u^+_0)
\]

for as long as \(u(t, u_0)\) exist. Since \(+ (t, u^+_0)\) and \(- (t, u^-_0)\) exist for all \(t \geq 0\), we would like to say that the same happens for \(u(t, u_0)\). This is going to be the case in a number of applications. Meanwhile, remaining abstract, we state the following result.

**Theorem 3.1.** Assume that \(A\) has compact resolvent and \(\text{Re}\sigma(A - c^+_1) > 0\).

i) If \(u(t, u_0)\) exists for all \(t \geq 0\) and remains bounded in \(X^\alpha\), then \(\omega(u_0) \neq \emptyset\) and

\[
(A - c^+_1)^{-1}c^-_2 = \Phi^+ \geq \phi \geq \Phi^- = (A - c^-_1)^{-1}c^-_2, \quad \phi \in \omega(u_0).
\]

ii) If (8) has a global attractor \(A\), then

\[
\Phi^+ \geq \phi \geq \Phi^- , \quad \phi \in A.
\]

In both cases the above results say that the order interval \(\{\phi \in X^\alpha : \Phi^+ \geq \phi \geq \Phi^-\}\) contains the asymptotic dynamics of (8).

The proof of Theorem 3.1 follows immediately from the fact that \(\Phi^+\) (or \(\Phi^-\)) is a global attractor for (12) (or (13)), from the definition of attractor and from (14).

Next we work towards obtaining the existence of global attractors for the problem (1). For that we need to introduce some additional structure. We have already checked, in Lemma 3.2 and in (14), that if \(X^{\alpha_0} \subset Y\) for some \(\alpha_0 > 0\) and (2) holds, then (8) has the following property:

\((H)\) Given a solution \(u(t, u_0)\) of (8) in \(X^\alpha\) on its maximal interval of existence \([0, \tau_{u_0})\), there are continuous functions \(\eta^+, \eta^- : (0, \infty) \rightarrow Y\) with \(\limsup_{t \rightarrow \infty} \|\eta^+ (t)\|_Y \leq K\) such that \(\eta^+(t) \geq u(t, u_0) \geq \eta^-(t), \quad t \in (0, \tau_{u_0})\).

**Assumption 3.1.** Assume \((H)\) implies that \(u(t,u_0)\) is globally defined, \(u(t,u_0) \in Y, \quad t > 0\) and

\[
\limsup_{t \rightarrow \infty} \|u(t,u_0)\|_Y \leq K.
\]

Assume also that \(\|f(u)\|_X \leq N_\eta\) whenever \(\|u\|_Y \leq K + \eta, \eta > 0\).

The Assumption 3.1 asserts that we are able to strengthen a global in time a priori estimate of \(u(t,u_0)\) in \(X\) (expressed as \(\eta^+(t) \geq u(t,u_0) \geq \eta^-(t)\)) to its global estimate in \(X^\alpha\) norm. Such property of solutions is usually a consequence of the structure of nonlinear term and the smoothing action of the solutions to (8).
Corollary 3.1. Assume that $f : X^\alpha \to X$ is Lipschitz continuous in bounded sets $B$-monotone map, (2) holds, $\text{Re}\sigma(A-c_1^+)>\mu_1>0$, $A$ has compact resolvent and Assumption 3.1 is satisfied. Then, the semigroup corresponding to (8) in $X^\alpha$ has a global attractor.

Proof: To prove this we proceed as follows. For $t \geq t_0 \geq 0$ we write

$$u(t, u_0) = e^{-A(t-t_0)}u(t_0, u_0) + \int_{t_0}^{t} e^{-A(t-s)}f(u(s, u_0))ds.$$ 

We now take $t_0$ large enough such that $\|u(s, u_0)\|_Y \leq K + \eta$ for $s \geq t_0$, which gives

$$\|u(t, u_0)\|_{X^\alpha} \leq M_0 e^{-\mu_1(t-t_0)}\|u(t_0, u_0)\|_{X^\alpha} + M_0 \int_{t_0}^{t} e^{-\mu_1(t-s)}(t-s)^{-\alpha}N_\eta ds$$

with $N_\eta = \sup_{\|s\|_Y \leq K+\eta} \|f(s)\|_X$. Since

$$\limsup_{t \to \infty} \|u(t, u_0)\|_{X^\alpha} \leq M_0 \int_{0}^{+\infty} e^{-\mu_1 z}z^{-\alpha}N_\eta dz = M_0 N_\eta \frac{\Gamma(1-\alpha)}{\mu_1^{1-\alpha}}.$$ 

and $\eta > 0$ is arbitrary, we conclude that

$$\limsup_{t \to \infty} \|u(t, u_0)\|_{X^\alpha} \leq M_0 N_\eta \frac{\Gamma(1-\alpha)}{\mu_1^{1-\alpha}}.$$ 

This shows point dissipativeness and, since the semigroup $e^{-At}$ is compact, we have that (8) has a global attractor (see [12], Theorem 4.2.4) and the result is proved.

4. APPLICATIONS

4.1. Ordinary Differential Equations

In this section we consider comparison results and existence of global attractors for systems of ordinary differential equations.

Let $F^+, F^- : \mathbb{R}^n \to \mathbb{R}^n$ be locally Lipschitz functions. Consider the initial value problems

$$\frac{d}{dt} \vec{x} = F^+(\vec{x}),$$
$$\vec{x}(0) = \vec{x}_0,$$ 

and

$$\frac{d}{dt} \vec{y} = F^-(\vec{y}),$$
$$\vec{y}(0) = \vec{y}_0.$$ 

Denote by $\vec{x}(t, \vec{x}_0)$ and $\vec{y}(t, \vec{y}_0)$ the solutions of (15) and (16), respectively.
Theorem 4.1. Assume that $F^+ \geq F^-$ and either $F^+$ or $F^-$ is a quasi-monotone increasing function (as in Subsection 2.2). If $\bar{x}_0 \geq \bar{y}_0$, then $\bar{x}(t, \bar{x}_0) \geq \bar{y}(t, \bar{y}_0)$ as long as both solutions exist.

Proof: Note that, fixed a bounded set $B$, either $F^+ + \beta B I$ or $F^- + \beta B I$ is increasing in $B$ for some $\beta_B \in \mathbb{R}$; therefore either $F^+$ or $F^-$ is a $B$-monotone map. Since $F^+ \geq F^-$, the theorem follows from the results in Subsection 2.1.

This comparison result has the following consequence concerning the problem (4).

Theorem 4.2. Let $F^+, F^- : \mathbb{R}^n \to \mathbb{R}^n$ be locally Lipschitz functions. Assume that either $F^+$ and $F^-$ are quasi-monotone or $F$ is quasi-monotone and $F^+ \geq F \geq F^-$. Under these assumptions

i) If $x_0 \geq z_0 \geq y_0$ and the solutions $\bar{x}(t, \bar{x}_0)$ of (15) and $\bar{y}(t, \bar{y}_0)$ of (16) are globally defined, then the solution $\bar{z}(t, \bar{z}_0)$ of (4) is globally defined.

ii) If $\bar{x}_0 \geq \bar{z}_0 \geq \bar{y}_0$ and the solutions $\bar{x}(t, \bar{x}_0)$ of (15) and $\bar{y}(t, \bar{y}_0)$ of (16) are globally bounded, then the solution $\bar{z}(t, \bar{z}_0)$ of (4) is globally bounded and $\omega(\bar{y}_0) \geq \omega(\bar{z}_0) \geq \omega(\bar{x}_0)$; that is, for any $a \in \omega(\bar{z}_0)$ there are $a^+ \in \omega(\bar{x}_0)$ and $a^- \in \omega(\bar{y}_0)$ such that $a^+ \geq a \geq a^-$. 

iii) If the problems (15) and (16) have global attractors $A^+$ and $A^-$, then (4) has a global attractor $A$ satisfying $A^+ \supseteq A \supseteq A^-$; that is, for any $a \in A$ there are $a^+ \in A^+$ and $a^- \in A^-$ such that $a^+ \geq a \geq a^-$. 

The proof of this result follows from the results in Subsections 2.2, 2.1 and properties of the global attractor.

4.2. Systems of Pseudodifferential Equations

As a second application we study global solvability and asymptotics of the problem

$$
\begin{align*}
  u_t + (-\Delta)^{\alpha} u &= f(u), & t > 0, & x \in \Omega, \\
  u(0, x) &= u_0(x), & x \in \Omega,
\end{align*}
$$

(17)

where $0 < \alpha \leq 1$ and $\Delta_N$ denotes the Laplace operator with Neumann boundary conditions in a bounded smooth domain $\Omega \subset \mathbb{R}^n$. This kind of problems have been studied recently in [7] and [8] in the case of $\Omega = \mathbb{R}^n$ and in [10] for bounded $\Omega$ with Dirichlet boundary condition. Here we obtain the existence of a global attractor as a consequence of comparison technique developed in previous sections. The results in this subsection remain true for the case $\alpha = 1$, treated in [6]. Thus, we concentrate our attention on the case $\alpha \in (0, 1)$.

In what follows, $X_0^\theta$, $0 \leq \theta \leq 1$, denote the fractional power spaces associated to $(-\Delta_N)$ in $L^p(\Omega, \mathbb{R}^m)$. In particular $X_1^\theta = \{ u \in W^{2,p}(\Omega, \mathbb{R}^m) : \frac{\partial u}{\partial n} = 0 \}$, and $X_0^\theta = X_\theta = L^p(\Omega, \mathbb{R}^m)$. For local well posedness of (17) in $X_\theta^\beta$ with $\beta < \alpha$, we assume that $f$ is locally Lipschitz and either $2\beta > \frac{\alpha}{p}$ or

$$
|f(u) - f(v)| \leq c|u - v|(|u|^{\rho - 1} + |v|^{\rho - 1} + 1), \quad u, v \in \mathbb{R}^m, \quad 1 \leq \rho \leq \frac{n}{n - 2\beta p},
$$

(18)
The order relation in $X$ is induced by the usual order in $\mathbb{R}^m$. From Proposition 5.4 (see Appendix) the resolvent of $-\Delta_N$ is increasing in $L^2(\Omega, \mathbb{R}^m)$. This property extends immediately to all $L^p(\Omega, \mathbb{R}^m)$ with $p \in (1, +\infty)$ by the usual density argument (see also [11], Theorem 1.3.9). As a consequence of formula (27) the resolvent of $(-\Delta_N)^\alpha$ remains increasing for all $\alpha \in (0, 1)$.

Next we summarize the comparison results for (17). Assume that $f^+, f^- : \mathbb{R}^m \to \mathbb{R}^m$ are locally Lipschitz continuous functions and consider the problems

\[ u^+_t + (-\Delta_N)^\alpha u^+_t = f^+(u^+), \quad t > 0, \quad x \in \Omega, \]

\[ u^+_0 = u_0^+ \in X^\beta_p, \tag{19} \]

and

\[ u^-_t + (-\Delta_N)^\alpha u^-_t = f^-(u^-), \quad t > 0, \quad x \in \Omega, \]

\[ u^-_0 = u_0^- \in X^\beta_p. \tag{20} \]

**Corollary 4.1.** Assume that $2\beta p > n$ and either $f^+$ or $f^-$ is quasi-monotone increasing. If $u^+_t(t, u_0^+)$, $u^-_t(t, u_0^-)$ denote the solutions of (19) and (20) respectively and $u_0^+ \geq u_0^-$, then $u^+_{t}(t, u_0^+) \geq u^-_{t}(t, u_0^-)$, for as long as both solutions exist.

**Proof:** Since $X^\beta_p \hookrightarrow L^\infty(\Omega, \mathbb{R}^m)$ and either $f^+$ or $f^-$ is quasi-monotone increasing, we obtain that the Nemytski˘ı operator associated to one of these functions is $B$-monotone in $X^\beta_p$. Therefore, the comparison for initial data in $X^\beta_p$ follows from Lemma 3.3.

The remaining results in this section have much simpler proofs in the case $2\beta p > n$. Hence, we concentrate on the case $2\beta p \leq n$. Assume that $f$ satisfies (18) and is quasi-monotone increasing.

**Remark 4.1.** A density argument may allow an extension of the above corollary to $X^\beta_p$, $2\beta p \leq n$, but we will not use this extension in what follows. Instead of this we use regularity properties of the solution.

For existence of attractors we assume that the following dissipativeness condition is satisfied

\[ \limsup_{|u_j| \to +\infty} \frac{f_j(u)}{u_j} < 0, \quad j = 1, \ldots, m. \tag{21} \]

For the long time behavior of the solutions it is important to obtain some a priori bounds. Often this is obtained with the aid of an energy functional. This idea may not be easily applicable in case of systems of equations where usually more delicate estimates are needed. This is why we are going to use comparison techniques to get the required bounds.

From (21) the condition (2) is satisfied with $c_1^+ \leq 0$.

Observe that if $u_0 \in X^\beta_p$ then $u(t, u_0) \in X^\alpha_p$ for $t > 0$. Since from Remark 4.2

\[ X^\alpha_p \hookrightarrow X^\beta_q, \quad p \leq q < p_1 = \frac{np}{n - 2(\alpha - \beta)p}, \]
then \( u(t, u_0) \in X_0^\beta, p \leq q < p_1 \). Repeating this argument with an initial data in \( X_0^\beta, q < p_1 \), we obtain that the solution enters \( X_0^\beta, p \leq q < p_2 = \frac{np_1}{n-2(\alpha-\beta)p_1} \). Inductively, \( u(t, u_0) \in X_0^\beta, p \leq q < p_j = \frac{np_{j-1}}{n-2(\alpha-\beta)p_{j-1}} \) for any \( j \in \mathbb{N} \). The sequence \( p_j \) is increasing and may not be bounded. If it was the case, its limit \( r \) would satisfy \( r = \frac{n}{n-2(\alpha-\beta)r} \).

This however would lead to the equality \( \alpha = \beta \) contradicting our hypothesis. Hence \( u(t, u_0) \in X_0^\beta \) for any \( q \geq p \). In particular, given \( u_0 \in X_0^\beta, u(t, u_0) \in X_0^\beta \) for \( t > 0 \) and \( 2\beta q > n \). Using any upper (lower) bound \( u_0^+ \in C \cap X_0^\beta \), \( (u_0^-, u_0^+) \in C \cap X_0^\beta \) for \( u(t_0, u_0), t_0 \in [0, \tau_{u_0}) \) fixed, we obtain as in Lemma 3.2 that

\[
\|u(t, u(t_0, u_0))\|_{L^\infty(\Omega, \mathbb{R}^m)} \leq M(u_0) t^{-\beta} + K, \tag{22}
\]

where \( K = \max\{\|((-\Delta)^\alpha - c_1^+)^{-1} c_2^+\|_{L^\infty(\Omega, \mathbb{R}^m)}, \|((-\Delta)^\alpha - c_1^-)^{-1} c_2^-\|_{L^\infty(\Omega, \mathbb{R}^m)}\} \). Since the solution does not blow up in the uniform norm, it must exist for all \( t \geq 0 \) and Assumption 3.1 is satisfied.

Corollary 3.1 now holds true and (17) has a global attractor \( \mathcal{A} \). Additionally, (22) yields

\[
\limsup_{t \to \infty} \|u(t, u_0)\|_{L^\infty(\Omega, \mathbb{R}^m)} \leq K.
\]

Remark 4. 2. Note that \([L^p(\Omega, \mathbb{R}^m), D(\Delta)]_\theta = H^{2\theta}_{p, N}, \text{ except for } 2\theta = 1 + \frac{1}{p}, \) (see [3], page 35), where \([\cdot, \cdot]_\theta\) denotes the complex interpolation functor of exponent \( \theta \in (0, 1) \) (see [20]). From embeddings for Bessel potential spaces and embeddings I.2.9.6 and I.2.5.2 in [4] we obtain

\[
X_0^\alpha \hookrightarrow [L^p(\Omega, \mathbb{R}^m), D(\Delta)]_{\alpha-} \hookrightarrow [L^p(\Omega, \mathbb{R}^m), D(-\Delta)]_{\beta+} \hookrightarrow X_0^\beta,
\]

for \( \beta < \beta^+ < \alpha^- < \alpha \) and \( 1 < p \leq q < \frac{np}{n-2(\alpha-\beta)p} \).

Remark 4. 3. The above considerations remain unchanged if instead of \( -\Delta_N \) we consider any second order uniformly strongly elliptic operator in divergence form. Also the boundary condition can be changed to a more general form \( b \frac{\partial u}{\partial \nu} = au \) provided that \( a, b \geq 0 \) and \( a^2 + b^2 \neq 0 \).

Consider now the fractional powers of second order uniformly strongly elliptic operators which are not in divergence form. Let \( a_{ij}, b_i, 1 \leq i, j \leq n, \Omega \) be sufficiently regular and \( L \) be the second order partial differential operator

\[
-Lu = \sum_{i,j=1}^n a_{ij}(x) \frac{\partial^2 u}{\partial x_i \partial x_j} + \sum_{i=1}^n b_i(x) \frac{\partial u}{\partial x_i}.
\]

As a consequence of a well known comparison result for parabolic equations (see [22], page 187), the analytic semigroup \( e^{-Lt} \) generated by the operator \(-L\) with Dirichlet bound-
ary condition is increasing. Therefore we can replace \((-\Delta_N)^\alpha\) in the equation (17) by a finite sum of fractional powers of \(L\).

### 4.3. Integral-Pseudodifferential Equations

Consider equations of the type:

\[
-\Delta_N^\alpha u(t, x) = f(u).
\]

(23)

As before \(\Delta_N\) denotes the Neumann Laplacian in \(L^p(\Omega, \mathbb{R}^m)\), \(p \in (1, +\infty)\), \(\alpha \in (0, 1]\), \(\Omega\) is a bounded smooth domain in \(\mathbb{R}^n\), \(u \in \mathbb{R}^m\), \(G : \Omega \times \Omega \to \mathbb{R}, G \geq 0, f : \mathbb{R}^m \to \mathbb{R}^m\) is quasi-monotone increasing.

For local well posedness of (23) in \(X^{\beta}_p\) with \(\beta < \alpha\) and \((X^{\theta}_p, 0 \leq \theta \leq 1\), as in Section 4.2) we assume that \(f\) is locally Lipschitz and either \(2\beta > \frac{n}{p}\) or (18) is satisfied. Let \(A = (-\Delta_N)^\alpha\) and assume that \(G\) is such that the operator

\[
v \xrightarrow{B} \int_{\Omega} G(\cdot, y)v(y)dy
\]

is bounded in \(X^p\) (for these conditions on \(G\) and estimates on \(\|B\|_{L(X^p)}\) in terms of \(G\) see [14], page 134).

The order relation in \(X^p\) is induced by the usual order in \(\mathbb{R}^m\). We need first justify that the semigroup generated by \(-A + B\) is increasing. Indeed, \(-A\) generates an analytic, increasing semigroup of contractions on \(X^{\beta}_p\). Since the integral kernel is nonnegative, \(e^{Bt}\) is increasing and the assumptions of Proposition 5.2 (see Appendix) are satisfied. Therefore, \(e^{(-A+B)t}\) is increasing. Also, since \(B\) is bounded, \(A - B\) is sectorial and the fractional power spaces corresponding to \((A - B)\) coincide with the fractional power spaces \(X^{\alpha}_p\) of \(A\) (see [13], page 29).

Next we summarize the comparison results for (23). Assume that \(f^{+}, f^{-} : \mathbb{R}^m \to \mathbb{R}^m\) are locally Lipschitz continuous functions and consider the problems

\[
\begin{align*}
&u^+_t + (-\Delta_N)^\alpha u^+ - Bu^+ = f^+(u^+), \ t > 0, \ x \in \Omega, \\
&u^+_0 = u^+_0 \in X^{\beta}_p,
\end{align*}
\]

(24)

and

\[
\begin{align*}
&u^-_t + (-\Delta_N)^\alpha u^- - Bu^- = f^-(u^-), \ t > 0, \ x \in \Omega, \\
&u^-_0 = u^-_0 \in X^{\beta}_p.
\end{align*}
\]

(25)

As in Corollary 4.1 we have:

**Corollary 4.2.** Assume that \(2\beta p > n\) and either \(f^{+}\) or \(f^{-}\) is quasi-monotone increasing. If \(u^+(t, u^+_0), u^-(t, u^-_0)\) denote the solutions of (24) and (25) respectively and \(u^+_0 \geq u^-_0\), then \(u^+(t, u^+_0) \geq u^-(t, u^-_0)\), for as long as both solutions exist.

Concentrating as before on the case \(2\beta p \leq n\) assume \(G\) is such that \(B \in L(X^q)\) for \(p \leq q \leq q_1\) with \(q_1 > \frac{n}{2\beta}\), \(f\) satisfies (18) and is quasi-monotone increasing.

PUBLICADO PELO ICMC-USP
SOB A SUPERVISÃO DA CPq/ICMC
For existence of an attractor we assume that the following dissipativeness condition is satisfied; there are positive constants $\xi_j$, $j = 1, \ldots, m$, such that

$$\limsup_{|u_j| \to +\infty} \frac{f_j(u_j)}{u_j} < -\|B\|. \quad (26)$$

From (26) the condition (2) is satisfied with $c_\pm < -\|B\|$.

Now, for a result similar to Lemma 3.2, we proceed exactly as in Subsection 4.2 using $K = \max\{\|((-\Delta)^\alpha - B - c_1^+)^{-1}c_2\|_{L^\infty(\Omega, \mathbb{R}^m)}\}$.

Corollary 4.2 now implies that the semigroup associated to (23) has a global attractor $A$ and

$$\limsup_{t \to \infty} \|u(t, u_0)\|_{L^\infty(\Omega, \mathbb{R}^m)} \leq K.$$

5. APPENDIX

Here we give conditions enabling us to obtain many operators with increasing resolvent starting from known increasing resolvent operator. In particular we need to know in which cases the sum of increasing resolvent operators has increasing resolvent and that a root of an increasing resolvent operator has increasing resolvent.

5.1. Operators with Increasing Resolvent and Increasing Semigroups

The following well known result establishes the equivalence between the monotonicity of the resolvent of a generator of a $C^0-$semigroup and the monotonicity of the semigroup itself.

**Proposition 5.1.** Let $(X, \leq)$ be an ordered Banach space, and let $A$ be a sectorial operator. Assume that there exists a $\lambda_0 \in \mathbb{R}$ such that $\text{Res}(A) > \lambda_0$. Then, $e^{-At} : X \to X$ is increasing for all $t \geq 0$ if and only if $(A + \lambda)^{-1}$ is increasing for every $\lambda > \lambda_0$.

The corollary below plays an important role in the proof of most comparison results presented in the paper.

**Corollary 5.1.** Let $(X, \leq)$ be an ordered Banach space, and let $A$ be a sectorial operator. Assume that for every $\lambda > \lambda_0$, $(A + \lambda)^{-1}$ is increasing. Let $u_\eta(t, u_0)$ denote the solution of

$$\dot{u} + Au = \eta u,$$

$$u(0) = u_0,$$

then, if $0 \leq u_1 \leq u_2$ and $\lambda < \mu$ we have that $u_\lambda(t, u_1) \leq u_\lambda(t, u_2) \leq u_\mu(t, u_2)$ for every $t \geq 0$.

Our next result provides conditions under which the sum of operators with increasing resolvent results in an operator with increasing resolvent.
THEOREM 5.1. Assume that $-A$ and $-B$ are generators of bounded $C^0$-semigroups, that $A$ and $B$ commute, the operator $A + B$ is closed, densely defined with domain $D(A) \cap D(B)$ and that $\lambda \in \rho(-A - B)$ for some $\lambda > 0$. Then $-A - B$ generates a bounded $C^0$-semigroup satisfying $e^{-(A+B)t} = e^{-At}e^{-Bt}$.

Proof: For a moment let us change the norm in the Banach space $X$ in such a way that $-A$ generates a $C^0$-semigroup of contractions. Let $-A_\lambda = -\lambda A(\lambda + A)^{-1}$ and $-B_\lambda = -\lambda B(\lambda + B)^{-1}$. Then $\|e^{-A_\lambda t}\| \leq 1$ for all $\lambda > 0$ and since $e^{-A_\lambda t}x \to e^{-At}x$ and $e^{-B_\lambda s}x \to e^{-Bs}x$ for all $x \in X$, $s, t \geq 0$, we have that

$$\lim_{\lambda \to \infty} e^{-A_\lambda t + B_\lambda s}x = \lim_{\lambda \to \infty} e^{-A_\lambda t}e^{-B_\lambda s}x = e^{-At}e^{-Bs}x.$$ 

Of course the above remain true if we change the norm to the original norm. Also, from a similar argument, we have that

$$\lim_{\lambda \to \infty} e^{-B_\lambda t - A_\lambda s}x = \lim_{\lambda \to \infty} e^{-B_\lambda s}e^{-A_\lambda s}x = e^{-Bs}e^{-At}x,$$

showing that $e^{-At}e^{-Bs} = e^{-Bs}e^{-At}$.

Let us now show that $T(t) = e^{-At}e^{-Bt}$ is a bounded $C_0$-semigroup with generator $-(A + B)$. First we observe that strong continuity at $t = 0$ and boundedness are clear and from

$$T(t + s) = e^{-A(t+s)}e^{-B(t+s)} = e^{-At}e^{-As}e^{-Bt}e^{-Bs} = e^{-At}e^{-Bt}e^{-As}e^{-Bs} = T(t)T(s)$$

we have that $T(t)$ is a semigroup. It remains to show that $-(A + B)$ is the generator of $T(t)$.

If $x \in D(A) \cap D(B) = D(A + B)$, then

$$T(t)x - x = \lim_{\lambda \to \infty} (e^{-A_\lambda t} - e^{-B_\lambda t} - x) = \lim_{\lambda \to \infty} (e^{-A_\lambda t} - e^{-B_\lambda t} + e^{-B_\lambda t}x - x) = \lim_{\lambda \to \infty} \int_0^t e^{-A_\lambda s}(-A_\lambda x) + \lim_{\lambda \to \infty} \int_0^t e^{-B_\lambda s}(-B_\lambda x)ds = \int_0^t e^{-As}e^{-Bt}(-Ax)ds + \int_0^t T(s)(-Bx)ds.$$ 

Now

$$\frac{1}{t}(T(t)x - x) = \int_0^t e^{-As}e^{-Bt}(-Ax)ds + \int_0^t T(s)(-Bx)ds \to -(A + B)x \text{ as } t \to 0^+,$$

for any $x \in D(A) \cap D(B) = D(A + B)$. Therefore the generator $-C$ of $T(t)$ must be an extension of $-(A + B)$. Let $\lambda$ be a real number in the resolvent of $A + B$ and in the resolvent of the generator of $T(t)$. Then

$$X = (\lambda + (A + B))D(A + B) = (\lambda + C)D(C),$$
hence $A + B = C$ and the proof is complete.

**Corollary 5.2.** If $-A$, $-B$, $-(A + B)$ are generators of $C^0$-semigroups, $A$ and $B$ commute and have increasing resolvent, then $-(A + B)$ has increasing resolvent.

The above results are closely related to the following results (see [21, 9]).

**Proposition 5.2.** Assume that $-A$ and $-B$ are generators of $C_0$-semigroups, $D(A) \cap D(B)$ is dense in $X$ and

$$\|(e^{-At}e^{-Bt})^n\| \leq Me^{\omega nt}, \quad n = 1, 2, \ldots,$$

for some constants $M \geq 1$ and $\omega \geq 0$. If for some $\lambda$ with $\text{Re}\lambda > \omega$ the range of $\lambda I + A + B$ is dense in $X$, then the closure of $-(A + B)$ is the generator of a $C^0$-semigroup $T(t)$ satisfying $\|T(t)\| \leq Me^{\omega t}, \quad t \geq 0$. Furthermore,

$$T(t)x = \lim_{n \to +\infty} \left(e^{-A(t/n)}e^{-B(t/n)}\right)^n x, \quad x \in X,$$

uniformly in bounded subsets of $\mathbb{R}^+$.

**Proposition 5.3.** If $-A$, $-B$, $-(A + B)$ generate $C^0$-semigroups, $\|e^{-(A+B)t}\| \leq Me^{\omega t}, \quad t \geq 0$, and

$$\|(I + tA)^{-1}(I + tB)^{-1}\|^n \leq Me^{\omega nt}, \quad n = 1, 2, \ldots,$$

then

$$e^{-(A+B)t}x = \lim_{n \to +\infty} \left[(I + \frac{t}{n}A)^{-1}(I + \frac{t}{n}B)^{-1}\right]^n x, \quad x \in X.$$

**Corollary 5.3.** If either the assumptions of Proposition 5.2 or the assumptions of Proposition 5.3 are satisfied, then

$$e^{-(A+B)t} \geq 0, \quad t \geq 0$$

or, equivalently, $(\lambda + A + B)^{-1}$ is increasing for $\lambda > \omega$.

For a proof of Proposition 5.2 and Proposition 5.3 see [18], §3.5. Corollary 5.3 provides tools to show that the resolvent of a sum of increasing resolvent operators is increasing, without the hypothesis that the operators commute. These will deal well with the case when the operators involved are dissipative. For some cases when the operators are not dissipative it may be more suitable to use Theorem 5.1.
The increasing resolvent property is preserved when we change the norm of the space to an equivalent one. This leads us to infer that it may be useful to know when one can change the norm of the space to an equivalent one in such a way to make \( A \) and \( B \) simultaneously dissipative. For considerations on this we refer to [18], § 1.5. The conditions on \( A \) and \( B \) that enable us to make this simultaneous change of norm are similar to the conditions in Propositions 5.2 and Proposition 5.3.

These results should contribute to enlarge the class of increasing resolvent operators that we can find. Our next result, being a slight extension of the Theorem 1.3.2 in [11], constitute an effort to simplify the verification that some operators have increasing resolvent.

**Proposition 5.4.** Let \( H \) be an ordered Hilbert space and \( C \) its positive cone. Let \( A : D(A) \subset H \rightarrow H \) be a self adjoint positive semi-definite operator, that is, \( \langle Au, u \rangle \geq 0 \) for all \( u \in D(A) \). Assume that \( H \) has a dense subset \( D \) such that:

- \((A + \alpha)^{-1}D \subset D\),
- For each \( d \in D \) we can define \(|d| = \sup\{d, -d\} \in D \cap C \) such that \( \|d\| = \||d|\| \) (this relationship satisfies: an element \( d \in D \) is in \( C \) if and only if \( d = |d| \)),
- \( |(d, g)| \geq |\langle d, g \rangle| \), \( \forall d \in D, \forall g \in C \).

Consider the following assertions:

(i) If \( u \in D(A^{\frac{1}{2}}) \) then \(|u| \in D(A^{\frac{1}{2}}) \) and

\[
\langle A^{\frac{1}{2}}|u|, A^{\frac{1}{2}}|u| \rangle \leq \langle A^{\frac{1}{2}}u, A^{\frac{1}{2}}u \rangle,
\]

(ii) \((A + \lambda)^{-1} \) is increasing for all \( \lambda > 0 \).

Then, (i) implies (ii).

### 5.2. Fractional Powers and Operators with Increasing Resolvent

Probably the most complete description of fractional powers of positive operators has been given by H. Komatsu in a number of papers written in middle 60’s. In particular in [15] we find the following definition of an operator \( A \) of type \((\omega, M(\theta))\), \( 0 \leq \omega \leq \pi \):

**Definition 5.1.** A densely defined closed linear operator \( A \) such that the resolvent of \(-A\) contains the sector \(|\arg\lambda| < \pi - \omega \) and

\[
\sup_{|\arg\lambda|=\theta} \|\lambda(A + A)^{-1}\| \leq M(\theta) < +\infty
\]

holds for \( 0 \leq \theta < \pi - \omega \) is called an operator of type \((\omega, M(\theta))\).

When \( \omega < \frac{\pi}{2} \) the above notion coincides with that of a positive sectorial operator as in [13]. Further in [15, p. 319], we find the formula describing the resolvent of fractional powers of \( A \) through the resolvent of \( A \). Namely, if \( A \) is of type \((\omega, M(\theta))\) and \( 0 < \alpha < \frac{\pi}{2} \),
then every $\lambda > 0$ is in the resolvent set $\rho((-A)^\alpha)$ and, for $\alpha \in (0, 1)$, the following equality holds:

\[
(\lambda I + (-A)^\alpha)^{-1} = \frac{\sin \frac{\pi \alpha}{\pi}}{\lambda^2 + 2\lambda \tau^\alpha \cos \pi \alpha + \tau^{2\alpha}} (\tau I + A)^{-1} d\tau.
\]

From above formula it is evident that the resolvent of $(-A)^\alpha$ is increasing for positive $\lambda$ whenever such property holds for the resolvent of $A$.

This result has been used in [10], when $-A$ is the Dirichlet Laplacian in a bounded smooth domain, to obtain an “integration by parts formula” for fractional powers of operators. This formula was important to obtain energy estimates that ensured the existence of attractors. Here instead of energy estimates we have used comparison results.

5.3. Consistence of the Ordering Induced in the Fractional Power Spaces

Finally we define an ordering in fractional power spaces of an ordered Banach space and state a result that shows the consistence of this ordering relation (see [6]).

Let $(X, \leq)$ be an ordered Banach space and $A$ be a sectorial operator in $X$. In $X^\alpha$, for $\alpha > 0$, we consider the ordering induced by $X$. The positive cone in each space $X^\alpha$ is denoted $C_\alpha$, $\alpha > 0$.

**Proposition 5.5.** With the ordering induced by $X$, $X^\alpha$ is an ordered Banach space, for any $\alpha \geq 0$. If $\alpha > \beta \geq 0$, then the inclusion $i_{\alpha, \beta} : X^\alpha \rightarrow X^\beta$ is increasing. Moreover, $C_\alpha \subset C_\beta$, $C_\beta \cap X^\alpha = C_\alpha$ and $\overline{C_\alpha X^\beta} = C_\beta$.

This shows the consistence of the definitions “$f \geq 0$”, independently of the space $X^\alpha$ in which $f$ lies. Therefore, we do not need to distinguish them.
